Seismic behavior of Pine Flat concrete gravity dam using microplane damage-plasticity model
Samuel Vorlet, Pedro Manso, Giovanni De Cesare
Alpine hydropower plants renewal: synergies between flexible production and hydropeaking mitigation

Motivation
Hydropoeaking is the water flow or level variations in rivers caused by hydropower exploitation. This phenomenon have negatives impacts on fauna and flora. Mitigation measures can lead to producing less and reduce production at the times that are most economically attractive. In a context where renewable energy production wishes to be increased and where operators wish to maintain their revenues, these measures are not satisfactory. This work aims to propose mitigation solution which keep production and flexibility constant or even increase them.

Methodology and indicators
Several variants and operating scenarios will be evaluated on construction cost, energy production, revenues and hydropeaking. Hydropeaking will be mainly evaluated with the indicators $I_A$. It will be considered problematic when its value is higher than 1.5.

$I_A = \frac{Q_t}{Q_{min}}$ : The hydropower plant exploitation discharge at time $t$

$Q_{min}$ : The minimum discharge in the river on the period studied

Studied case
The case study is composed of 5 hydropower plants located in the Upper-Rhône Basin. Among these installations, Heiligkreuz is subject to an order of hydropeaking sanitation. Hydropeaking have been detected between Heiligkreuz and Ze Binnen and also downstream Mörel power plant.

Variants and operating scenarios will be evaluated on construction cost, energy production, revenues and hydropeaking. Several variants and operating scenarios will be evaluated on construction cost, energy production, revenues and hydropeaking.

Discussion
Variants studied allow to improve production and to mitigate hydropeaking on Heiligkreuz section but replace river section with residual flow. Ecological benefits induced by this replacement are not proved yet. The scenario “Null Hydropeaking” allow to delete hydropeaking on Mörel river section but cause a flexibility loss showed by a revenues reduction.

Suspended sediment in the turbine water of HPP Fieschertal in 2018

Matthias Eugster, David Felix, Robert Boes; VAW, ETH Zürich

Introduction

Sediment particles transported in the water of mountain rivers (Fig. 1) cause hydro-abrasive erosion on turbines of medium and high-head Hydro-Power Plants (HPP). This reduces the turbine efficiency and electricity production while the costs for repairs and spare parts increase. As a basis for economic optimizations, this study aimed at quantifying the Suspended Sediment Load (SSL) in the penstock of the high-head HPP Fieschertal in the Swiss Alps throughout the year 2018.

Set-up

The HPP Fieschertal is a run-of-river scheme (Fig. 2) downstream of the Fieschergletscher which is the second longest glacier in the Alps. In the valve chamber (Fig. 3), (1) an acoustic discharge measurement installation (ADM), (2) a Coriolis Flow and Density Meter (CFDM), (3) a Laser In Situ Diffractometer (LISST) and (4) an automatic water sampler were operated to measure the suspended sediment concentration (SSC). In addition, particle size distributions between 3 and 380 µm were measured by LISST every minute.

Methods

From each water sample, the SSC was determined by weighing in the laboratory (gravimetrical method). Using these reference SSC and the median particle size $d_{50}$ obtained from LISST, the SSC were evaluated from the raw data recorded by the other instruments. The SSC from the ADM were found to be most reliable for SSC < 0.5 g/l, whereas the data of the CFDM were preferred > 1 g/l. Between 0.5 and 1 g/l, a weighted average of SSC from ADM and CFDM was used.

The Suspended Sediment Load (SSL) in the penstock was calculated by integrating the product of SSC and discharge over time.

Results

Suspended sediment concentration (SSC)

Suspended sediment particles were mainly transported from mid April to mid November 2018 (Fig. 4). Some SSC peaks, e.g. on June 11 (day 161), are due to rain events, but no major flood occurred in 2018. The highest SSC in the penstock was caused by a re-suspension event in the storage tunnel (Fig. 2) on August 14 (day 225): When the water level in the tunnel was drawn down while the turbines were running, the flow velocity and the bottom shear stress in the tunnel increased. This led to the transport of more and coarser particles into the penstock compared to normal operating conditions in summer when the tunnel is completely filled with water and acts a secondary trap for fine sand.

Suspended sediment load (SSL)

In 2018, about 86 000 t of mainly silt particles were transported through the penstock, corresponding to a specific fine-sediment yield of 0.6 mm per year in the catchment area of 58 km². While the average SSC was similar to previous years, a relatively high runoff volume due to the warm summer (glacier melt) led to a rather high SSL.

In contrast to the year 2012 with a major flood event, the sediment transport rate was quite uniform during the summer months of 2018. Hence there was no need to temporarily shutdown the HPP in this year.

Conclusions

The SSL in the power waterway of HPPs depend not only on the weather conditions but also on the HPP operation. The annual sediment loads vary considerably mainly due to occasional flood events. Therefore, long-term data series are required to obtain reliable average values and to capture the full variability of the processes. Real-time suspended sediment monitoring serves as a basis for economic and energetic optimizations of HPP operation. Thus it contributes to the sustainable and efficient use of the hydropower potential and hence to the implementation of the Energy Strategy 2050.

Renewal of alpine hydroelectric plants according to the spatial and temporal scales of analysis

Vincent GAERTNER, Sabine CHAMOUN1, Pedro MANSO1, Giovanni DE CESARE1
1 Hydraulic Constructions Platform (PL-LCH), EPFL

Introduction
Since the adoption of the “Energy Strategy 2050” by the Federal Council in 2017, Switzerland is looking for new energy sources to replace the nuclear sector and ways to reduce its greenhouse gas emissions, in particular by promoting the development of renewable energies. The national hydroelectric park, which represents 55% of total energy production, has an essential place in this context of upheaval in electricity supply. In the coming years, more and more existing power plants will come to the end of the concession. In this transitional period, they must be the subject of interventions to adapt their installations and operations to future economic, energy, legislative and environmental contexts. The main objective of the project is the development of a methodology to identify and promote technical solutions to increase winter energy production and operating flexibility. It consists of a first step of diagnosing the installations reference state and then a second step of generating and analysing renewal variants. It is then applied to the case study of the Forces Motrices de Conches (GKW) and the Forces Motrices Valaisannes (FMV) power plants in Haut-Valais.

Methodology
The general methodology followed in this work consists of three main steps. First of all, the establishment of the existing system reference state aims to study the existing power plants and their environment in order to choose the spatial and temporal scales of analysis and to identify the potential for optimising operation. Renewal variants are generated according to the identified intervention possibilities. These variants are then compared using multi-criteria analysis, modelling and pre-dimensioning to produce final recommendations. The choice of the spatial scale of analysis is intended to limit the scope of investigations for the generation of renewal variants. The approach of choice proposes to evaluate at different scales the additional potential of existing facilities and their environment in order to achieve the project objectives. If large-scale surveys are required, a simplified cost calculation of an extension of storage capacity should allow for a comparison of construction costs and potential winter production gains. Preselection is carried out to evaluate and compare the variants using criteria on energy, technical, environmental and social aspects. Finally, a second comparison based on the results of this in-depth analysis should lead to recommendations for final solutions.

Case study
The project applies to the Heiligkreuz (GKW), Ernen and Mörel (FMV) power plants located on the left bank of the Rhône in Haut-Valais, Switzerland.

Rivers and intakes in the study area are not instrumented and the required hydrological data are only partially available. The operating data from the Heiligkreuz, Ernen and Mörel power plants and the Rhône flow measurements at Reckingen provided by the FOEN are therefore used to reconstitute the water inflow curves at the intakes.

Results
The procedure for generating adaptation concepts enables the development of 18 local variants and sub-variants based on the intervention types identified in the previous step. They can be divided into two main groups according to whether they aim to specifically optimize the use of Lengtalwasser inflows or whether they propose to exploit the potential of the Saflischthal. The three of them that are preselected provide an increase in production thanks to two new power plants and seasonal storage possibilities thanks to a large capacity reservoir upstream of Kummenbord and new pumping systems between Ze Binnen and Kummenbord. Hydraulic modelling of operating scenarios and energy performance assessment show an increase in the annual production of the three main power plants.

The development of scenarios based on the seasonal transfer of inputs also provides an opportunity to rebalance the annual distribution of production by increasing winter supply.

The economic evaluation of the variants shows a decrease in the profitability of the largest variants due to high construction costs. A balance must therefore be found between the advantages of winter supply and the expected financial benefits.

Conclusions
The application of the methodology to a case study in Upper Valais provided different variants to achieve the objectives of increasing energy production and developing operational flexibility and seasonal storage for winter supply. It has been established that the GKW and FMV power plants in the Conches Valley have a real potential for optimization. Variants with large storage capacities have been selected and submitted for further study. Finally, modelling and pre-dimensioning steps demonstrated their relevance to the project objectives. One of the avenues for continuing the project could be the instrumentation of strategic points of the system in order to ensure better monitoring of the available hydrological inflows and to consider optimising operation up to the limits of the current and future concession.

Comissioning of a new fatigue test rig based on pressure oscillations

A. Gaspoz¹, N. Gonçalves¹, L. Barras¹, V. Hasmatuchi¹, C. Nicolet², S. Rey-Mermet¹
¹HES-SO Vaud, School of Engineering, powder technologies and advanced materials Group, CH-1950 Sion, Switzerland, samuel.rey-mermet@hevs.ch
²Power Vision Engineering Sàrl, Chemin des Champs Courbes 1, CH-1024 Ecublens, Switzerland

Context

Hydraulic power plants are an important part of the electricity production. Most of installations have been built before the 80’s. The maintenance and the research of defects are the base to ensure their security. Fatigue phenomenon appears faster when the parts contain defects.

To study the behavior of a defect under pressure oscillation, a special test rig was build in the HES-SO laboratory in Sion. The idea consists to create periodically water hammer with a rotating valve and use the resonance (sum) phenomenon in the middle of the pipe. The oscillations are comparable to those present in a penstock and responsible of a fatigue break.

Methods

The commissioning started at the end of 2018 and the characterisation of the test rig was realized whit pressure sensors during spring 2019. Numerical simulation have permit to design and chose the different operating point. Simulation were realised with the software Simsen [1] marketed by Powervision Engineering in Ecublens, Switzerland.

Characterisation Results

Curves of energy losses in function of the flow and the valve’s position.

Numerical Results

Pressure amplitude on the test section, directly upstream of the valve and the pump normalized by the values of the main operating point.

The pressure amplitude directly upstream of the valve is equal to half that present in the test section.

The transient characteristic of the valve was simulated with the open source software OpenFOAM. The result is used in Simsen for the global transient simulation.

Conclusion

✓ The test rig is in function and the last corrections are planned for the end of 2019.
✓ The principle of cyclic water hammer in resonance was measured and corresponds to the transient simulations.
✓ The installation of a crack sensor has started this year. The sensor is marketed by Sensima and uses the Foucault current effect to measure the depth and the length of a crack [2]
✓ The first break of pipe should be realized by the end of 2019.

Hydraulics of Horizontal Bar Rack-Bypass Systems: Field Study at HPP Stroppel
Roland Hagenbüchli, Ismail Albayrak, Mohammadreza Maddahi, Ricardo Mendez, Robert M. Boes

Introduction
Horizontal bar rack-bypass systems (HBR-BS) are widely used for fish protection and guidance at hydropower plants (HPP). In 2014 a HBR-BS was installed at Stroppel HPP located on River Limmat in Switzerland. Axpo Power AG as the HPP operator and Aquarius [1] conducted an extensive fish monitoring campaign at this HPP in 2015 – 2017. In the present study, the hydraulics of the HBR-BS were investigated and linked to the results from the fish monitoring campaigns.

Study Site HPP Stroppel
Stroppel HPP is the most downstream power plant on the River Limmat before its confluence with the River Aare. Table 1 lists the main characteristics of the HPP and its HBR-BS system.

Methods
An Acoustic Doppler Current Profiler (ADCP) mounted on a remote controlled boat with RTK-GPS was used to investigate the hydraulics of the HBR-BS (Fig. 1). Velocity measurements were conducted in 13 cross-sections normal to the flow direction in the headrace channel and in two sections parallel to the rack (Fig. 2). In addition, six stationary measurements were conducted at selected positions as shown with red crosses in Fig. 2.

Results and Discussion
Figure 3 shows the depth-averaged velocity magnitudes along the headrace channel. The vectors indicate longitudinal and transverse velocity directions. The velocity field shows that the main flow has the tendency to shift towards the left side, where the bypass entrance is located. Furthermore, due to the low ratio of channel width to flow depth y, the flow is 3D and the maximum velocities are concentrated at the channel center and below the water surface (Figs. 3 and 4).

References
Introduction

Low-level outlets are key safety elements of high-head reservoir dams. The load on low-level outlets will likely increase in the near future due to more frequent sediment flushing and dam heightening. Therefore, an improved understanding of their hydraulic properties is necessary. A common outlet configuration uses a high-pressure vertical slide gate discharging into a free-flow tunnel. The high-speed water jet in the outlet tunnel leads to considerable air entrainment and transport resulting in negative air pressures, which can aggravate problems with gate vibration, cavitation, and slug flow. Sufficient air supply via an air vent mitigates such problems. However, current methods for estimating the required air demand do not incorporate all factors affecting design of air vents for low-level outlets. Additionally, information on two-phase flow hydraulics regarding e.g. flow pattern or mixture flow depth is almost inexistent. The hydraulics of low-level outlets were investigated in a doctoral thesis using hydraulic model tests, prototype measurements and numerical simulations. The main findings are summarized herein.

Results

Air-water flow pattern

Four different air-water flow pattern were observed in the model and prototype tests:
- Spray flow; for relative gate openings ≤ 0.12 and contraction Froude numbers \( F_c \geq 40 \)
- Free-surface flow; significant shockwave formation due to detachment of corner vortices was observed for 0.3 ≤ relative gate opening ≤ 0.7 (Fig. 1a).
- Slug flow; strong counter-current air flow can trigger the formation of slugs. A novel flow pattern map allows to identify and consequently avoid slug flow (Fig. 1b).
- Pressurized flow; for relative tunnel fillings ≥ 0.8 the downstream tunnel end was pressurized.

Air demand

The influence of air vent, tunnel length \( L_t \) and tunnel slope \( S_t \) on the relative air demand \( \beta \) of low-level outlets was studied in extensive model tests. The air demand is primarily a function of \( F_c \) and the air vent properties. Increasing \( L_t \) leads to an increase in air demand, the effect of \( S_t \) is small. Prototype measurements were used to validate and extend the model-based results leading to a new predictive equation:

\[
\beta = \frac{Q_a}{Q_t} = 0.08 F_c^{-0.2 \left( \frac{A}{A (\zeta + 1)^2} \right)^{0.25} \left( \frac{L_t}{h_t} \right)^{0.25}}
\]

where \( A \) = tunnel area, \( A_{air} \) = air vent area, \( h_t \) = tunnel height, \( Q_{air} \) = air discharge through air vent, \( Q_{water} \) = water discharge, \( \zeta \) = air vent loss coefficient.

Equation 1 captures the available prototype data roughly within ±50%, thus considerably improving air demand predictions compared to order of magnitude errors of existing approaches.

Figures

Figure 1: (a) gate vortices observed in model tests; pressurized air added for visualization. (b) Flow pattern map to identify slug flow; lines denote different probabilities of slug formation. \( h_u \) = energy head at gate, \( p_{min} \) = minimum air pressure in gate chamber.

Figure 2: Comparison of (a) observed prototype air demand versus predicted \( \beta \) (Eq. 1). (b) relative error versus predicted \( \beta \).

Hydraulics air-water flow

High velocities of up to 22 m/s in model tests allowed to gather data at prototype like conditions leading to the following results:
- Void fraction \( \zeta \); the void fraction profile can be described by an advection-diffusion equation (Fig. 3a). The mean void fraction \( C_{mv} \) reaches a maximum after the gate and decreases from thereon.
- Interfacial velocity \( u \); a wall-jet like profile was observed close to the gate, whereas a velocity-dip profile occurred further downstream. The latter can be described with a novel modified power law (Fig. 3b).
- Mixture flow depth \( h_{mix} \); the development of \( h_{mix} \) can be described with a novel empirical approach based on a simplified backwater calculation (Fig. 3c).

Figure 3: (a) \( C_{mv} \) profile for different \( C_{uw} \). (b) \( u \) profile at different dimensionless distances, \( h_u \) = contraction flow depth. (c) Simplified backwater curve \( h_{cr} \); \( h_u \) = critical flow depth, \( h_u \) = uniform (non-aerated) flow depth, \( S_t \) = tunnel slope.

Conclusions

A detailed model study on air-water flows in low-level outlets was conducted. The results were complemented by prototype measurements. The findings presented herein allow for an improved design of low-level outlets for future infrastructure adaptions.

This project is financed by the SNF Grant No. 163415 and is embedded in the SCCER-SoE framework. The prototype tests were financially supported by the Lombardi Engineering Foundation and conducted in cooperation with Ofibite.
Numerical investigation of HPP layouts and their effects on fish guidance racks

Andreas Huwiler

Introduction
Hydro power plants (HPP) inhibit downstream fish migration. Fish guidance structures (FGS) can be used to improve this situation. The goal of this study was to analyze the upstream flow fields at different HPP layouts. The analyses were conducted with computational fluid dynamics (CFD). The effect of different measures at the HPP layouts to fish guidance structures were investigated.

Background
There are different concepts to ensure downstream fish migration. One criterion for good fish guidance efficiency is the ratio between the velocity parallel ($v_p$) and the velocity normal to the rack ($v_n$). This ratio ($R_v$) should be higher than one [1]. In this study, horizontal bar racks (HBR) were investigated since HBRs have little influence on the flow field. Different physical studies were conducted at the VAW to investigate HBR [2]. At HBRs, the ratio depends mostly on the HPP layout. The layout influences the approach flow to the turbines and to the rack, as can be seen in figure 1. The pillar at the bay unit HPP layout (1b) improves the ratio in front of the rack.

Methodology
Using CAD Software a block unit HPP, a bay unit HPP and a HPP with side intake were built (fig. 2). Based on this layouts different simulations were conducted with the CFD Software FLOW-3D. The HBR was substituted as a baffle. The analysis of the approach flow of the rack was of particular interest. Furthermore, the influence of different discharges over the weir and different angles of the rack to the fish guidance were examined.

Results and Discussion
The flow field was analyzed with horizontal planes of the flow velocity in x-direction ($U$) and different cross sections (CS). The most important CS was the one along the rack where the $R_v$ was plotted. Figures 4 and 5 of the simulated and measured results of the block unit HPP are shown as examples. The simulated data represents the measured data in a high agreement. Differences in the horizontal flow field are direct in front of the weir and after the rack. At the CS along the rack, the biggest differences can be identified direct at the weir on the left side of the plot. The plot illustrates how the fish guidance worsens along the rack towards the weir ($R_v < 1$).

Conclusion
The results of different CFD simulations at a block unit HPP could be verified with measurements from a physical model. Thus, the HBR could be well implemented as a baffle in FLOW-3D. Additional HPP layouts were analyzed. There, the influence of different rack angles and discharges on the FGS could be quantified. Both measures can be used to improve the $R_v$. Which measure should be implemented depends on the studied layout and existing restrictions.

Run-up of Impulse Wave Trains
Maximilian Kastinger, Frederic Evers, Robert Boes

Introduction
Very rapid gravity-driven mass movements including landslides, rockfalls, avalanches and glacier calvings can cause large water waves in open oceans, bays, natural lakes and reservoirs. Resulting impulse wave trains propagate away from the impact location and can run up several meters high on the shore. Possible consequences are damages to settlements and infrastructure or overtopping of dams, as shown by numerous historic events in Switzerland and abroad. Reservoirs are of particular interest, as there is usually a freeboard of just a few meters to settlements and infrastructure or overtopping of dams, as shown by several meters high on the shore. Possible consequences are damages to

While the run-up of single and periodic waves has already been extensively researched, there is only few knowledge about the multiple run-up of irregular wave trains. Therefore, the aim of this master’s thesis was to investigate the run-up behavior of impulse wave trains and to develop an approach in order to estimate their run-up heights.

Methodology
Physical model tests were carried out in a 2D wave channel. The waves were generated by mesh-packed granular material sliding into the water body. First, the unconfined wave propagation was measured with ultrasonic distance sensors (UDSs). Then, the experiments were repeated with a barrier of different slope angles \( \beta \), which was installed at the location of one of the sensors. The run-up was recorded with cameras. Fig. 1 shows the test setups for unconfined and run-up experiments.

**Fig. 1:** Test setup for (a) unconfined wave propagation, (b) wave run-up at a vertical barrier and (c) wave run-up at an inclined barrier, exemplarily being installed at the location of UDSs.

Different wave characteristics were achieved by varying the water depth \( h \), slide angle \( \alpha \), impact velocity \( V_i \), sliding mass \( m_s \) and grain density \( \rho_g \). Target wave properties include the wave crest and trough amplitudes \( a_c \) and \( a_t \) respectively, wave heights \( H_i \), wave celerities \( c_i \), wave periods \( T_i \) and wave lengths \( L_i \). The wave run-up \( R_i \) refers to the still water table, as shown in Fig. 2.

**Fig. 2:** Definition scheme with the governing parameters for (1) wave generation and (2) wave run-up

Results and Discussion

Breaker types
A different run-up behavior of the waves was observed. It was divided into non-breaking (NO), surging breaker (SU) and plunging breaker (PL). Fig. 3 illustrates these three types for an exemplary experiment.

As the breaker type influences the run-up height significantly, a prediction criterion based on the surf similarity parameter \( \xi = \tan(\beta)(H_i/L_i)^{1/2} \) (Iribarren and Nogales, 1949) and the relative wave height \( H_i/h \) is proposed (Fig. 4).

**Fig. 3:** Run-up behavior of the first four waves for a barrier slope angle \( \beta = 26.6^\circ \), the first two waves are non-breaking (NO), the third wave is a surging breaker (SU) and the fourth wave is a plunging breaker (PL)

Non-breaking waves (NO):
\[
\xi > 2 \left( \frac{H_i}{h} \right)^{0.5}
\]

Surging breakers (SU):
\[
1.5 \left( \frac{H_i}{h} \right)^{0.5} \leq \xi \leq 2 \left( \frac{H_i}{h} \right)^{0.5}
\]

Plunging breakers (PL):
\[
\xi < 1.5 \left( \frac{H_i}{h} \right)^{0.5}
\]

**Fig. 4:** Surf similarity parameter \( \xi \) versus relative wave height \( H_i/h \) for the different breaker types and the proposed criteria

Run-up heights
A new prediction equation for the run-up heights is proposed (Eq. (3)). Fig. 5 shows the measured over predicted run-up heights. While non-breaking waves and surging breakers are represented well, plunging breakers are overestimated.

**Fig. 5:** Measured over predicted (Eq. (3)) run-up height \( R_{\text{meas}}/R_{\text{pred}} \) versus relative wave crest amplitude \( a_c/h \)

\[
\frac{R_{\text{meas}}}{R_{\text{pred}}} = \frac{\xi^{0.25} (90^\circ)^{-0.5}}{a_c} \left( \frac{0.9 \xi}{\sqrt{8g}} \right)^{1/2}
\]

Conclusion
A new data set with run-up heights of impulse wave trains for later reuse was created. Based on this, a new breaker type criterion and run-up prediction equation are proposed. Tests with additional barrier slope angles and further data analysis are required in order to develop a well-founded, practicable run-up equation for impulse wave trains.

References
Why ?

For many dam operators, their assets are aging in a context that evolves both with new flood assessment methods and new legal or normative frameworks. Building new outlet structures to ensure enough flood release capacity can be expensive and limited. Figure 1 presents the reason for submergence acceptability assessment for a generic case, based on a real dam [1].

The proposed method

Divided in four modules, the method offers a framework to consider the different inputs necessary to assess the risk of dam instability due to scour following dam submergence (Fig. 2), due to insufficient conventional spilling capacity. The vulnerability to scour formation is assessed based on the duration of the submergence events, on the geometry of the falling nappes, on the downstream tailwater levels and on dam foundation & riverbed rock conditions. Then, scour evolution is assessed through different methods, considering to some extent the complexity of the processes taking place during scour progress by the interaction of air, water and rock.

EPFL’s Comprehensive Scour Model (CSM) [1] illustrates a possible way to sequentially link several physical processes, one of them being time-dependent. Rock fracture propagation under hydrodynamic loads is modelled using the Paris- Erdogan fatigue law and hydrodynamic loads defined according [2,3,4,6]. Recently, a novel EBM model was proposed by [5] considering only the Excess Energy (EEBM) available for scour at each given moment. The four previous methods allow having multiple truncated entries to inform decisions and risk assessment. Figure 3 graphically shows the required data to properly calibrate such methods.

Submergence can be an alternative, but the dam stability has to be guaranteed and therefore it raises a few questions:
- Can the dam withstand higher reservoir levels above the crest?
- Which flood events can be accepted?
- What is the acceptable residual risk?
- To which extent is dam toe scour acceptable, considering the dam’s or the abutment’s instability?

This last question can be the most challenging one.

Results

The general method was applied to two different dams. The first one is a dam located at a high altitude with a fairly small reservoir and ungated crest overflow spillway. A Piano Key Weir spillway was added recently to ensure enough capacity for the revised millennial flood. The second dam is quite different, situated at intermediate altitudes and equipped with a three-bay gated spillway with ski-jumps for a total capacity of 5800 m³/s. The study of the first dam revealed that no scour had occurred yet in over 50 years. The scour analysis with USM methods showed that some erosion could occur for extreme flood events with a return period of 5000 years or more. However, the EEBM time-accounting method [5], based on the potentially available energy for scour, showed that the flood event duration was too short for any serious erosion to occur. For the second case study, with gated spillways, the available plunge pool bathymetries and spillage records allowed obtained site constants of scour progression (according [8]) and estimating scour from extreme events. The application of the EEBM showed interesting results as well, indicating that instead of using site constants to calibrate Spurr’s scour evolution function, one should rather use event-related constant for calibration of such function (i.e. the same event might not produce the same scour increase if occurring at different chronological moments in the spillage records).

Further application of these methods could help to better assess how rock quality, discharge intensity and duration are linked to the equilibrium state of a scour pool. Indeed, better knowledge of possible scour evolution can help with assessing the acceptability of dam submergence.

Solving of a Lifting Problem in a Pumped Storage Power Plant

Daniel Pace, Giovanni De Cesare, Pedro Manso, Kaspar Vereide, Livia Pitorac, Leif Lia
Email: daniel.pace@alumni.epfl.ch

Motivation

The construction and upgrading of pumped storage hydropower plants (PSHP) will be very beneficial in the years to come to regulate the power systems. They are very flexible and allow covering peak demands and storing energy on a large scale. In this work, the Duge PSHP in Norway is used as a case study. The power plant has two Francis reversible pump-turbines (RPT) with a total installed capacity of 200 MW. In 2017, however, the turbines were refurbished and since then, a lifting problem occurs at the rotor of one of the turbines (Unit 1) when generating at a high load. As a consequence of this problem, the generation has to be restricted to 80% of the maximal load, i.e. 160 MW. The aim of this work is to understand the causes of the lifting and to find a civil engineering solution to this problem by modifying the waterway of the power plant.

Results

In order to solve the lifting problem, three solutions have been selected. The first aims to avoid any problems in the worst load case and to be able to run the power plant at 200 MW again. The second aims to avoid any problems in a normal load case and to run at 200 MW as well. Finally, the third solution aims to be lighter on a technical and economic point of view and to be able to run the power plant at 185 MW. For each solution, the downstream pressure is compared to the unmodified power plant.

Solution 1
- Addition of a downstream air cushion surge tank
- Addition of a 6 km parallel tunnel in the tailrace

Solution 2
- Increase of volume in the surge tank upper chamber
- Addition of a 6 km parallel tunnel in the tailrace

Solution 3
- Addition of a 6 km parallel tunnel with smaller section in the tailrace

After an economic analysis is made, the final costs for each solution are estimated considering the construction works (new access tunnels, excavation, draining of tailrace tunnel, etc.) and the losses due to the power plant outage. The costs are given in different currencies (1 NOK = 0.1177 CHF and 1 NOK = 0.1008 EUR):

Methods and materials

The Duge PSHP has a very long tailrace tunnel (12 km) in comparison to the headrace tunnel (650 m). The high friction losses due to the long tailrace give a high downstream pressure rise at the RPT units in generating mode.

In order to propose modifications of the power plant, a model is made on LVTrans, a numerical modelling freeware allowing to calculate transients in a loaded pipe system [1]. To simulate the real behaviour of the prototype, the model is calibrated against downstream pressure measurements, done at the draft tube wall for a turbine shutdown.

The calibration is considered satisfactory, since only the first pressure peaks, which are the worst, are of interest for the lifting problem. The lifting of the rotor (246 tons) at Unit 1 occurs when the resulting vertical force acting on the runner is directed upwards; the downstream pressure is therefore the significant factor to consider. Norconsult, a Norwegian consulting company, calculated that 1 [mWC] downstream pressure change ± 4.1 [tons] of lifting force. This is obtained by multiplying the pressure by the surface of the outlet. Moreover, the maximal lifting force acting on the runner should be no more than 75 tons [2]. Considering this, it is possible to have a threshold that the downstream pressure should not exceed in order to safely run the power plant without the lifting problem.

Discussion

As showed in the results, the modifications of the power plant improve both the steady and unsteady states and allow the downstream pressure at Unit 1 to remain under the critical threshold. However, the solutions seem to be disproportionate, considering the total amount of the required investments and construction works. A limitation of the economic analysis is that only the total costs are considered, but not the associated benefits of having more power available.

Finally, the Duge power plant will receive new runners in the future, which means that the problem may be solved in a few years. Considering all these conclusions, it seems that it is probably better to not opt for a civil engineering solution to solve this lifting problem.

Renewal of the Ritom hydropower plant

Jakob Siedersleben, Samuel Vorlet, Giovanni De Cesare, Nicola Tatti, Urs Müller, Graziano Sangalli

Context
On the basis of the Water Protection Act of 2013, a new generation of regulating reservoirs is under construction across Switzerland. It requires that all Swiss operators of hydroelectric power plants must eliminate within 20 years all severe issues caused by the rapid change of water discharge, called hydropeaking, due to the exploitation of hydrodynamic power. In Tessin, the hydroelectric power plant constructed in 1921 will be modernized. In the framework of this modernisation a new powerhouse with three machine groups will be constructed. In order to minimize the effects of hydropeaking, a regulating reservoir with a volume of 100,000 m$^3$ is planned. The discharge exiting the reservoir can be controlled by a regulating structure which leads the water via an outlet in the Ticino. Due to the new reservoir, the course of the river Foss has to be changed and four sills will be installed. Fig. 1 shows the current and the planned situation.

Results
The tests showed a well-functioning of the whole system. But the course of the Foss had to be adapted. Furthermore, rock sills were installed and the roughness of the riverbed was increased. With these adaptations the desired maximum capacity of $Q_{Foss} = 60$ m$^3$/s is exceeded. Dependent on the discharge combination of the Ticino and the outlet of the regulating structure, one must expect sediment accumulation either at the outlet of the regulating reservoir or at the embouchure. Furthermore, one must expect a scour hole dependent on the discharge at the outlet of the regulating reservoir and the discharge of the Ticino as illustrated in Fig. 3. However, the main influence on the depth of the scour hole is the discharge in the outlet of the reservoir.

Physical Modelling
The modelled area is 215.2 m long in flow direction of the Ticino and 181.2 m wide perpendicular to the flow direction. The modelled area is illustrated in Fig. 1. The model was constructed with a scale of 1:40 according to the Froude similitude.

Objectives
The Laboratory of Hydraulic Constructions of the EPFL was mandated to execute experiments on a physical model. The following objectives were determined for the project:

- Concept validation of the planned geometry of the Ticino, the regulating reservoir and the Foss
- The investigation of the influence of the regulating structure on the Ticino
- The behaviour of the whole system under flooding up to an EHQ (extreme flood)
- The analysis of floating debris and debris flow in the Ticino and the Foss

In order to analyse the model, the water heights are measured at eight locations with ultrasound sensors. The height of the riverbed is measured with a red laser on a grid of twenty-five points. The flow velocities are measured with a current meter at three points. The physical model and the measuring positions are illustrated in Fig. 2. Furthermore, visual observation and colorant was used to determine dead and recirculation zones and determine possible locations prone for deposition of sediments.

Hydro-abrasion at hydraulic structures

Damiano Vicari, Dila Demiral, Ismail Albayrak, Robert M. Boes
ETH Zurich, Switzerland

Motivation and objectives

Sediment transport from glacier basins, rivers and waterways have strongly increased under the effect of climate change. As a consequence, high sediment transport rates combined with high flow velocities cause severe hydro-abrasion at hydraulic structures such as Sediment Bypass Tunnels (SBTs) and bedrock incision in high-gradient mountainous streams. A better understanding of the physical processes of turbulent flow characteristics, bedload particle motion, and hydro-abrasion and their interrelations is of prime importance for both sustainable use of hydraulic structures and landscape evolution. Therefore, this study aims at (1) investigating turbulence characteristics of supercritical open-channel flows, (2) conducting hydro-abrasion experiments at the same flow conditions as in (1) to determine the abrasion depths and patterns, and (3) data evaluation and calibration of the abrasion prediction model.

Experimental setup and test program

The experiments were conducted in a b = 0.2 m wide, h = 0.5 m deep and l = 13.5 m long glass and wood-sided laboratory flume with Sb = 1% bed slope (Fig. 1). The first 5 m of the flume is covered with a non-erodible concrete followed by 6.6 m erodible foam. The supercritical open channel flow conditions were provided by a gate controlled jetbox system that converts the pressurized conduit flow into the free surface channel flow. The experiments were conducted with flow depths h = 10 and 20 cm with Fb = 2, 3 and 4 at four sediment supply rates Qs = 100, 200, 400 and 800 g/s (Table 2). Polyurethane foams were placed to the flume bottom with decreasing material strength in the flow direction (Fig. 1). Flow depths were measured using an Ultrasonic Distance Sensor (UDS) and a Distance Laser Device (DLD) mounted on a traverse system consisting. The surfaces of the foams were scanned using a 3D Leica P15 laser scanner after each run with 1 ton of sediment supplied to the flow. The obtained data were used to determine the development of hydro-abrasion pattern and rates.

Results and discussion

Figure 2 presents the contour maps of final surfaces for the experiments E1 and E2. It shows that hydro-abrasion pattern is dominated by an incision channel along the flume center, growing and enlarging in time. Such pattern is triggered by saltation of bed load particles transported by the flow at the flume center where the bed shear stresses are higher compared to flume side walls. Results also show that for the same amount of sediment transport i.e. 1 ton, the abrasion depths are similar in the two test runs, independent from the sediment supply rate, Froude number, and aspect ratio.

Conclusions and outlook

An experimental investigation was conducted to understand the bed abrasion mechanism in supercritical narrow open channel flows existing in hydraulic structures and steep bedrock rivers. Results show that hydro-abrasion develops in the flume center creating a continuous incision channel and such pattern is independent from the Froude number and aspect ratio in the range of b/h < 2. Vertical abrasion rate Ar linearly increases with increasing bedload rate, whereas it decreases with increasing bed lining material strength. The Froude number affects the abrasion rate. The findings of this study provide knowledge basis to better understand on hydro-abrasion mechanism and hence lead us to develop a hydro-abrasion prediction model.

Seismic behavior of Pine Flat concrete gravity dam using microplane damage-plasticity model

Samuel Vorlet, Pedro Manso, Giovanni De Cesare

Introduction
The response of gravity dams under seismic loads is a major concern of dam safety assessment in earthquake-prone areas. The dynamic response of the dam body depends to some extent on the binding foundation conditions as well as on the interaction with the reservoir. During earthquakes, gravity dams are subject to strong horizontal and vertical motions inducing stresses with peaks that may be greater than the maximal strength and consequently lead to damage in the dam body, mainly in tension state. Currently, most dam safety evaluations with finite elements (FE) analysis of reservoir-dam-foundation systems consider a linear elastic model for mass concrete with failure criteria based on maximal tensile strength [1,2], in particular for the non-extreme load combinations. First assessments of extreme load combinations using linear analyses allow preliminary estimates of the location and extent of tensile stress peaks greater than the maximal concrete tensile strength but cannot inform on stress and stiffness redistribution during an earthquake (damage time evolution). This study concerns linear and nonlinear analyses with damage model in order to assess the dam safety under seismic loads resulting with stress peaks leading to damage in the dam body. It presents the seismic analysis of Pine Flat Dam for the 15th International Benchmark Workshop on Numerical Analysis of Dams to be held in Milan in September 2019. It focuses on the tallest non-overflow monolith of Pine Flat concrete gravity dam located on King’s River, east of Fresno, California (USA).

Methods
Numerical simulations were performed using the finite element code ANSYS (M-APDL) to discretize the governing equations on the computational domain. A two-dimensional finite elements (FE) model of the reservoir-dam-foundation system is considered. The dam is composed of 37 monoliths and its crest is 561 m long. The tallest non-overflow monolith is 121.91 m high with a 95.8 m base length. The dam body and rock foundation (700 m x 122 m) are modeled with quadrilateral structural plane strain elements. The reservoir is modeled using acoustic elements with inviscid and compressible.

For damage modeling in the dam body, a coupled damage-plasticity model for concrete [3] based on microplane formulation [4, 5] is used. The model has the ability to define different damage initiation criteria and damage evolution laws between tension and compression states. The model can additionally represent cyclic loading conditions, where stiffness lost during cracking is recovered due to crack closure during transition from tension to compression state, while damage sustained under compression remains upon transition to tension state [3].

Dynamic properties

Figure 1: Reservoir-dam-foundation FE model boundary conditions and interfaces

For damage modeling in the dam body, a coupled damage-plasticity model for concrete [3] based on microplane formulation [4, 5] is used. The model has the ability to define different damage initiation criteria and damage evolution laws between tension and compression states. The model can additionally represent cyclic loading conditions, where stiffness lost during cracking is recovered due to crack closure during transition from tension to compression state, while damage sustained under compression remains upon transition to tension state [3].

Figure 2: Natural frequencies and mode shapes; Winter Reservoir Water Level (WRWL); Summer Reservoir Water Level (SRWL)

Figure 3: Computed horizontal displacements at crest and heel of the dam; (a) WRWL; (b) SRWL; Taft Record acceleration

Figure 4: Computed horizontal displacements at crest and heel of the dam; (a) Taft Record acceleration, no failure; (b) artificially designed ETAF acceleration, failure

Figure 5: Computed damage parameter DMG; (a) Taft Record acceleration, no local dam failure; (b) artificially designed ETAF acceleration, failure of the dam body

Conclusions
Results show the ability of the numerical models to: (i) reproduce adequately the dynamic properties of the reservoir-dam-foundation system and (ii) conduct dynamic linear and nonlinear analysis. Results of nonlinear analyses show the ability of the model to represent cyclic loading conditions, with recovery of the stiffness lost during cracking in the transition from tension to compression state, and subsequent failure of the dam body near the crest.
